STAT243 Problem Set2

Name: Chih Hui Wang SID: 26955255

September 5, 2015

1. (a) I will use R and bash to deal with the problem. Use bash to make the size of file small and R to do random sampling. Firt, I use **curl** to download the bz2 file. and rename it as **PS2data.bz2**. At this point, we are not allowd to directly unzip the data, so I use the modifier **-c** to output the content to observe data. It will not directly unzip the file.

```
#Download
curl -s "www.stat.berkeley.edu/share/paciorek/ss13hus.csv.bz2" -o PS2data.bz2
#Show data
bunzip2 -c PS2data.bz2 | head -n2
```

Now we turn to R to do some processing. Change my R working directory to **Work**, and use **list.files()** to check whether I am in the right directory.

```
setwd("/home/oski/Work")
#To check we are in the correct working directory
list.files()

[1] "PS2data.bz2" "#ps2.lyx#"   "ps2.lyx"     "ps2.lyx~"    "ps2.r"
```

Because we only need certain column, I use **read.csv** to get the first row and later use R to process it. To avoid the string setting as factor, I use **stringsAsFactors**=**FALSE**.

```
allcol <- read.csv("PS2data.bz2", nrow=1, header=FALSE, stringsAsFactors=FALSE)
```

To see where those columns locate, I use **%in%**, which give us a row of TRUE/FALSE,and **which** , which give me the location,to get which columns are those we want. Then, output the result to number.csv and I can use cut in bash to retrieve those row to decrease the file size.

```
#Column we want
col_want <- c("ST", "NP", "BDSP", "BLD", "RMSP", "TEN", "FINCP",
                          "FPARC", "HHL", "NOC", "MV", "VEH", "YBL")

#Find out which column we want to keep
coln_want <- which(allcol %in% col_want)
#Output the result for bash
write.table(coln_want, "number.csv", row.name=FALSE, col.name=FALSE)
```

I store the column number in variable **number**. I use sed to replace the space by **,** because when using the modifier **-f** for **cut**, we use **,** as seperator for column. For example, to pull out one and second columns → cut -d',' -f1,2 filename.

After we got those numbers for columns we want, we can use cut to take out those column and pipe it into command **gzip** to zip the result, named PS2data.gz.

```
#Get the colname we want
col_n=$(cat number.csv)
#Get all the column number
number=$(echo $col_n | sed 's/ /,/g')
echo $number
#Eliminate other columns and zip the result
bunzip2 -c PS2data.bz2 | cut -d',' -f$number | gzip -c > PS2data.gz
```

```
8,12,17,18,32,41,45,47,49,50,53,63,64
```

Before I start to write my function, I need to know how many rows in the data which then I can sample the row Index from it. I use **readLines** and file connection here. It will read 100000 row for each time until there are no data anymore by **while** loop. I initialize l by 1 to start the while loop, so in the end I have to substract 2 from **total_row**, 1 for the l and 1 for the header.

```
total_row <- 0
datacon <- file("PS2data.gz", open="r")
#Initial
l <- 1
while(l > 0){
        total_row <- total_row + l
        l <- length(readLines(datacon, n=100000))
}
close(datacon); rm(datacon)
total_row <- total_row - 2
#Total number of row in the data
total_row
```

```
[1] 7219000
```

my.read.csv contain 3 arguments, file's name **(filename)**, number of sample **(n)**, number of total row **(total_row)**, how many rows we want to read each time **(maxrow)**. I first creat a variable, **breaks**, containing numbers from 1 to 7300001 by every 100000 for later usage. The reason to use 7300001 is that there are data from row 7200001 to 7219000. Then the function will first create a all-0 data frame by n and the length of colname. To avoid the mismatch name, it does not use the colname users provide; instead, it reads the first line, gets its name and puts it to our all-0 data frame. After sampling **(row_want)**, it uses file to open a reading connection, which can help us keep the pointer and escape the slow speed by skipping large number. Then it runs a for-loop which containing the process of reading 100000 each time (**read.csv** with argument **nrow=maxrow**) and also finds the corresponding row we want in our sample **(row_want)** as well as updates the row index **j**. Finally it closes the connection and renders the sample data for user.

There are several points that I should clarify in my function. First, the reason why I do not use the **col_want**(previous variable) as the name of the data is that when we compare the name by **%in%** and **which**, the output will not give location exactly same as the order of our col_want. Hence, it may be safer to directly use data name. Second, when I wirte the for loop, I use **length(breaks) - 1**. Because the last number of breaks is 7300001 which is bigger than the length of our data, it should not go through the operation in the for loop. Thrid, I use **file** function to create a reading connection here. By doing so, I can avoid use the **skip** function in **read.csv** which makes the speed of reading the data in the last very slow; in other words, I have to skip a large number of row.

```
#function
my.read.csv <- function(filename, n, total_row,maxrow=100000){
                upper <- (total_row %/% maxrow) + 2
                breaks <- seq(1, maxrow*upper + 1, by=maxrow)
                datacon <- file(filename, open='r')
                col_name <- read.csv(datacon, nrow=1, header=FALSE, stringsAsFactors=FALSE)
                data <- matrix(0, nrow=n, ncol=length(col_name))
                data <- as.data.frame(data)
                #Avoid miss match
                names(data) <- col_name
                #Sample
                n.row <- sample(1:total_row, n)
                #Index
                j <- 1
                for(i in 1:(length(breaks) - 1)){
                        row_want <- which(n.row >= breaks[i] & n.row < breaks[i + 1])
                        if(length(row_want) == 0){
                                next
                        }else{
                        data[j:(j + length(row_want) - 1), ] <- read.csv(datacon, nrow=maxrow, header
                        j <- j + length(row_want)
                        }
                }
                close(datacon)
                data
}
set.seed(1)
newdata <- my.read.csv("PS2data.gz", n=10000, total_row, maxrow=100000)
write.csv(newdata, "NewPS2data.csv", row.names=FALSE)
head(newdata)

  ST NP BDSP BLD RMSP TEN VEH YBL FINCP FPARC HHL MV NOC
1  1  4    3   2    7   1   2   7 68800     2   1  5   2

```

(b) In this problem, I will compare three way to read the data and sample it, which is **read.csv**, **read_csv**, **readLines**. My function's strutcure will basically be the same as the one I write about (**my.read.csv**). I finished the one for read.csv.

Now, let us first deal with the function for **read_csv** in the package ***readr***. For **read_csv**, the connection will be unable to use. When it read by the connection, it will automatically close the connection; therefore we lose the pointer which make me have to use **skip** argument in it. Although using **skip** for **read_csv** will be faster than **read.csv**, its speed is still very low.

```
library(readr)
my.read_csv <- function(filename, n, total_row, maxrow=100000){
                upper <- (total_row %/% maxrow) + 1
                breaks <- seq(1, maxrow*upper + 1, by=maxrow)
                col_name <- names(read_csv(filename, n_max=1))
                data <- matrix(0, nrow=n, ncol=length(col_name))
                data <- as.data.frame(data)
                #Avoid miss match
                names(data) <- col_name
                #Sample
                n.row <- sample(1:total_row, n)
                #Index
                j <- 1
                for(i in 1:(length(breaks) - 1)){
                        row_want <- which(n.row >= breaks[i] & n.row < breaks[i + 1])
                        if(length(row_want) == 0){
                                next
                        }else{
                                data[j:(j + length(row_want) - 1), ] <- read_csv(filename, n_max=maxr
                                j <- j + length(row_want)
                        }
                }
                data
}

set.seed(1)
data <- my.read_csv("PS2data.gz", n=10000, total_row, maxrow=100000)
```

```
|=                                                                      |   1%     3 MB
|=                                                                      |   1%     3 MB
|=                                                                      |   2%     3 MB
|=                                                                      |   2%     3 MB
|=                                                                      |   2%     3 MB
|==                                                                     |   2%     3 MB
|==                                                                     |   2%     3 MB
|==                                                                     |   2%     3 MB
|==                                                                     |   3%     3 MB
```

```
|==                                                                    |   3%     3 MB
|==                                                                    |   3%     3 MB
|===                                                                   |   4%     3 MB
|=====                                                                 |   6%     3 MB
|===========                                                           |  13%     3 MB
```

```
head(data)
```

```
  ST NP BDSP BLD RMSP TEN VEH YBL FINCP FPARC HHL MV NOC
1  1  4    3   2    7   1   2   7 68800     2   1  5   2
2  1  6    2   2    6   1   4   7 41000     2   1  3   2
3  1  2    2   2    5   2   0   3 58000     4   1  1   0
4  1  2    3   2    5   1   3   6 91000     4   1  6   0
5  1  2    3   2    6   2   2   7  9900     4   1  5   0
6  1  2    2   2    6   4   2   5 28800     4   1  3   0
```

The next one is **readLines**. It read in each line as a character. Hence, without any processing, I cannot just put the sample into the all-0 data frame. Since the file is seperate by ,. I can use the function **strsplit** to split the character into different columns by ,. However, when I do this operation, some rows' length is not 13 which is our total column number. The probelm present as below. If there is a space next to the last comma, the **strsplit** function will not give us that space. To addfress this problem, I use **gsub** which replace all the **,** by **,** (with a space in the end). Then using the **strsplit**, I can get the last space, but another problem occurs. After spliting, the class of the output is list. My strategy is to make the data into a numeric matrix by the function, unlist and putting it into another matrix. By doing so, I can input the value into our data frame.

```
eg <- "I,am,"
strsplit(eg, split=",")
```

```
[[1]]
[1] "I"  "am"
```

```
my.readLines <- function(filename, n, total_row, maxrow=100000){
                upper <- (total_row %/% maxrow) + 1
                breaks <- seq(1, maxrow*upper + 1, by=maxrow)
                datacon <- file(filename, open="r")
                col_name <- strsplit(readLines(datacon, n=1), split=",")[[1]]
                data <- matrix(0, nrow=n, ncol=length(col_name))
                data <- as.data.frame(data)
                names(data) <- col_name
                #Sample
                n.row <- sample(1:total_row, n)
                j <- 1
                for(i in 1:(length(breaks) - 1)){
                        row_want <- which(n.row >= breaks[i] & n.row < breaks[i + 1])
                        if(length(row_want) == 0){
                                next
                        }else{
                                data_row <- readLines(datacon, n=maxrow)[n.row[row_want] - breaks[i]
```

```
                                process <- as.numeric(unlist(strsplit(gsub(",", ", ", data_row), spli
                                process_matrix <- matrix(process, nrow=length(row_want), ncol=length(
                                data[j:(j + length(row_want) - 1), ] <- process_matrix
                                j <- j + length(row_want)
                        }
                }
                close(datacon)
                data
}

set.seed(1)
data <- my.readLines("PS2data.gz", n=10000, total_row, maxrow=100000)
head(data)

  ST NP BDSP BLD RMSP TEN VEH YBL FINCP FPARC HHL MV NOC
1  1  4    3   2    7   1   2   7 68800     2   1  5   2
2  1  6    2   2    6   1   4   7 41000     2   1  3   2

6  1  2    2   2    6   4   2   5 28800     4   1  3   0
```

The last one is kind of a mix for above funtion(**readLines** and **read.csv** or **read_csv**). I notice that the **readLines** with connection is really fast when reading data. I take advantage of this point; however I do not make any processing in my for-loop. Instead, I just retrieve those row I want by **readLines**. To solve the problem, I can use the **writeLines** function to write the output into csv file and use read_csv to read the csv file. Therefore, I can save some time for processing the output of **readLines**.

```
library(readr)
my.read.mix <- function(filename, n, total_row, maxrow=100000){
                upper <- (total_row %/% maxrow) + 1
                breaks <- seq(1, maxrow*upper + 1, by=maxrow)
                datacon <- file(filename, open="r")
                data <- matrix(0, nrow=n + 1)
                data[1] <- readLines(datacon, n=1)
                #Sample
                n.row <- sample(1:total_row, n)
                #Index
                j <- 2
                for(i in 1:(length(breaks) - 1)){
                        row_want <- which(n.row >= breaks[i] & n.row < breaks[i + 1])
                        if(length(row_want) == 0){
                                next
                        }else{
                                data[j:(j + length(row_want) - 1)] <- readLines(datacon, n=maxrow)[n.
                                j <- j + length(row_want)
                        }
                }
                close(datacon)
                writeLines(data, "data.csv")
                read_csv("data.csv")
}
```

```
set.seed(1)
data <- my.read.mix("PS2data.gz", n=10000, total_row, maxrow=100000)
head(data)

For overall speed performance, **readLines** is faster than **read.csv** and **read.csv** is faster than **read_csv**. The reason why **readLines** is so fast is that it only read line by line data withou processing and putting them into data.frame while the **read.csv** does. I think why **read_csv** is slow in this situation is that when it read the compressed file, it will automatically uncompress it. Also, I do not find a method to use connection with **read_csv** which forces me to use the argument skip. Therefore, whenever it read the data in for-loop, it will uncompress the file. I believe that it is the main reason why **read_csv** cannot outperform over **read.csv** in this case. Actually, I tried to unzip the file and use the similar function(as **my.read_csv**) to read it. Its performance may not be slower than **my.read.csv**.

```
system.time(my.read.csv("PS2data.gz", n=10000, total_row, maxrow=100000))

(c) I have done it first when I read in the data, which is that I eliminated the column. The dim of processed data is 7219000x13. Compared to the original data, it reduced large size so I can read it faster.

(d) First of all, I make sure every column have the same value or range as the description. Indeed, the range is correct. I will select some variables to make some tables or graphs to detect wether there is any interesting relationship between variable.

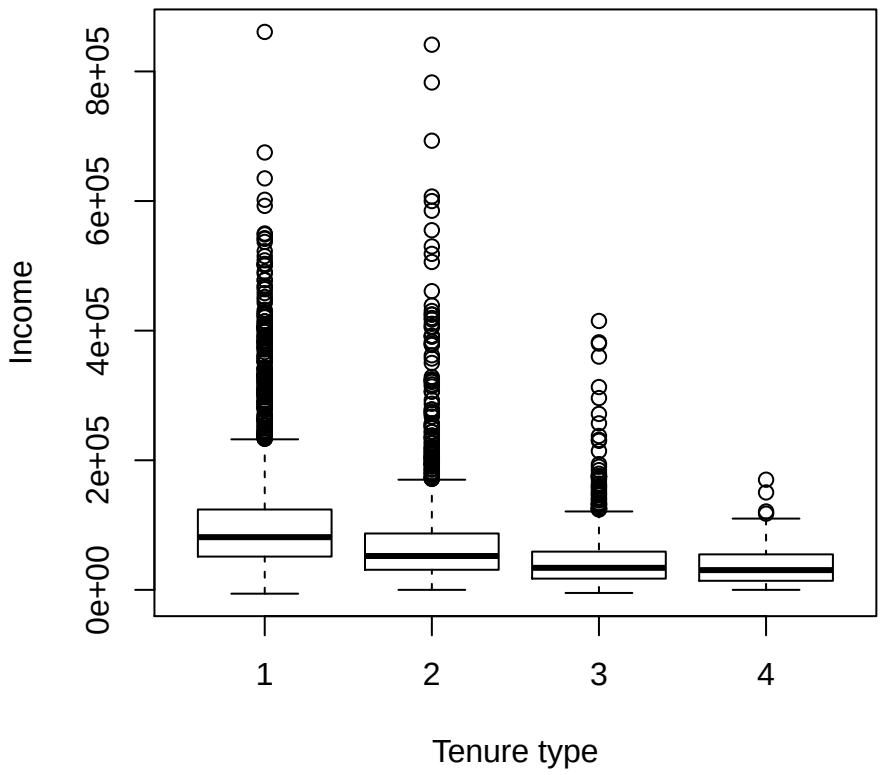
First I compare two variable FINCP(family incom) and TEN(tenure). Originally, I think those family who have a higher income may not have house mortgage which should belong to second category in TEN(own free and clear). However, it turns out that overall family who owns mortgage may have a higher income, although the difference may not be statistically siginificant.

```
with(data, boxplot(FINCP ~ TEN, xlab="Tenure type", ylab="Income"))
```



Then I want to see the distribution of HHL(household language) among ST(state code). It is quite hard to detect any pattern by table. Therefore, I try to visualize them in a better way.

```
#Table
round(with(data, prop.table(table(HHL, ST), 2)), 2)

   ST

```

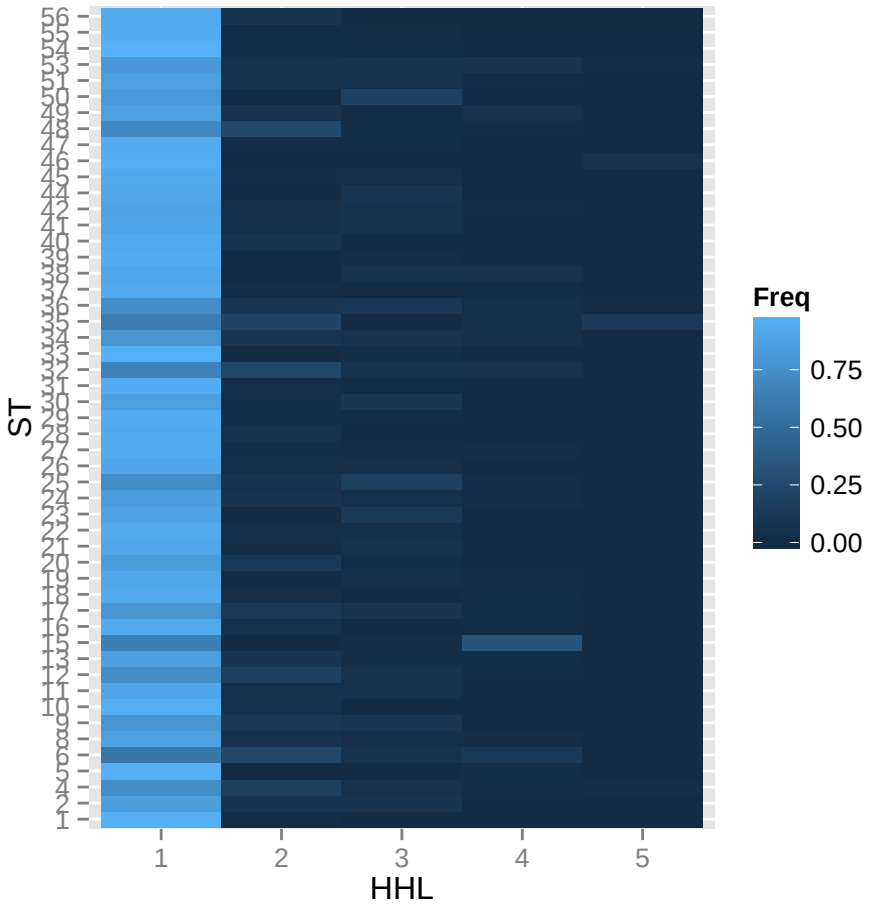
I used the ggplot to visualize the table by tile plot(geom_tile). We can find that there may be other second languages in household for those state coded as 48, 35, 32, 15, 6. It turns out that #48 is Texas, #35 is New Mexico, #32 is Nevado, #15 is Hawaii and #6 is California. Hawaii's Second language is other Indo-European languages while other states are Spanish.

```
t <- as.data.frame(round(with(data, prop.table(table(HHL, ST), 2)), 2))
library(ggplot2)

Loading required package:  methods

#Visualize
ggplot(t) + geom_tile(aes(x=HHL, y=ST, z=Freq, fill=Freq))
```



Lastly, I make a table for NP(number of person records following the house) and vehicle. I find that some family only have few person record like 2, 3 or even 1, but they have 4 or more vehicles, which is quite strange. Maybe they have different vehicle for diferent purpose.

```
with(data, table(NP, VEH))
```

```
    VEH
NP      0    1    2    3    4    5    6
  0     0    0    0    0    0    0    0
